Care and Use of Dogs

The Occupational Health Program is designed to inform individuals who work with animals about potential zoonoses (diseases of animals transmissible to humans), personal hygiene and other potential hazards associated with animal exposure. This information sheet is directed toward those involved in the care and use of dogs.

Potential Injury & Zoonotic Diseases

Dogs are very social animals and respond to human interaction and affection. When injured or ill, they can become frightened and agitated, and they will bite and resist being handled. In the research setting, exposure to dogs can pose potential health risks to humans, such as infection from dog bites and scratches, allergic responses, and exposure to pathogenic enteric organisms through accidental fecal/oral contact. There are many organisms that may not produce symptoms in dogs but can cause diseases in people. The most common of these disease causing organisms are discussed below.

**Rabies:** Rabies virus (rhabdovirus) can infect almost any mammal; however, it is very rare in the research environment because dogs are purchased from high quality sources with excellent vaccination and disease control programs. The source of infection to people is an infected animal. Dogs shed the virus in their saliva 1-14 days before developing clinical signs. Any random-source (animal with an unknown clinical history) or wild animal exhibiting central nervous system signs that are progressive should be considered suspect for rabies. Transmission is through contact with saliva, mucus membranes, or blood, e.g. bite or saliva on an open wound. Symptoms are pain at the site of the bite followed by numbness. The skin becomes quite sensitive to temperature changes and laryngeal (throat) spasms are present. Muscle spasms, extreme excitability, and convulsions occur. Rabies in unvaccinated people is almost invariably fatal. *Rabies vaccine* is available through UCD Occupational Health Services.

**Brucellosis:** The bacterial organism, *Brucella canis*, is found in dogs and swine breeding colonies where it will be manifested by abortions and reproductive organ infections. Transmission of *B. canis* to humans is not clear but probably occurs through oral or transcutaneous (skin) contact with organism-infected blood or other tissues. The disease in humans may mimic the flu with symptoms such as fever, headache, fatigue, muscle and joint pain. Rare complications include arthritis, meningitis and endocarditis. There is no cure for brucellosis in animals, but humans respond to antibiotic treatment over a course of 4 to 6 weeks.

**Ringworm:** Dermatophyte infection (most commonly *Microsporum* spp. and *Trichophyton* spp.) is commonly known as ringworm because of the characteristic circular lesion often associated with it.
Dermatophytes are classified as fungi and may not be readily apparent. Disease in people is from direct contact with an infected animal. Ringworm is usually self-limiting and appears as circular, reddened, rough skin. It is responsive to prescription topical therapy.

**Tuberculosis**: This disease may be transmitted to people through contact with birds, livestock, canines, and non-human primates. Tuberculosis is usually transmitted by the aerosolization of infective bacilli which can be found in sputum, as well as other body fluids. Contact with aerosolized body fluids during necropsy may be a major mode of transmission to humans. Pulmonary tuberculosis is the most common type of TB in humans, but other organs may also be involved.

**Leptospirosis**: It is bacteria found in many animals but are most commonly associated with livestock and dogs. The source of infection can be from any of the following: rats, mice, voles, hedgehogs, gerbils, squirrels, rabbits, hamsters, reptiles, dogs, sheep, goats, horses, standing water. Leptospires are in the urine of infected animals and are transmitted through direct contact with urine or tissues via skin abrasions or contact with mucous membranes. Transmission can also occur through inhalation of infectious droplet aerosols and by ingestion. The disease in people is a multi-systemic disease with chronic sequelae. An annular rash is often present with flu like symptoms. Cardiac and neurological disorders may follow, and arthritis is a common end result.

**Other Diseases**: There are several other diseases that can be possibly spread through working with dogs. *Cryptosporidia, giardia, campylobacter* and *salmonella* are transmitted via the fecal/oral route. These diseases in people are exhibited by acute gastrointestinal illness (diarrhea, nausea, vomiting, abdominal pain and fever). Clinical signs are generally brief and self-limiting.

**Allergic Reactions to Dogs**: Individuals who have been previously sensitized to dogs outside of the work place may be at greater risk of developing allergies to dogs. Exposure to dog allergens is via saliva, hair, and skin.

**How to Protect Yourself**

- **Wash your hands.** The single most effective preventative measure that can be taken is thorough, regular hand washing. Wash hands and arms after handling dogs. Never smoke, drink or eat in the animal areas or before washing your hands.

- **Wear gloves.** When working with dogs wear appropriate gloves for the task and wash your hands after removing gloves.

- **Wear respiratory protection.** Dust masks should be worn if there is a personal history of allergies to dogs and when there is a risk of aerosol transmission of a zoonotic agent. An N-95 should be worn.

- **Wear other protective clothing.** Lab coats or coveralls should be available and worn when working with the dogs. Avoid wearing street clothes while working with animals.

- **Seek Medical Attention Promptly.** If you are injured on the job, promptly report the accident to your supervisor, even if it seems relatively minor. Minor cuts and abrasions should be immediately cleansed with antibacterial soap and then protected from exposure to dogs. **All dog bites should be treated at Occupational Health Services.**
Tell your physician you work with dogs. Whenever you are ill, even if you’re not certain that the illness is work-related, always mention to your physician that you work with dogs. Many zoonotic diseases have flu-like symptoms and would not normally be suspected. Your physician needs this information to make an accurate diagnosis. Questions regarding personal human health should be answered by your physician.
